

Linebooker Logistics SaaS - System Context

Scope: the proposed Linebooker Logistics SaaS is the one software system in scope. Audience: business stakeholders, product teams, architects and new engineers. Internal applications, services, stores, NATS topology and regional deployment are deliberately deferred.

Person or internal role System in scope External system Synchronous interaction Pushed event or telemetry

IdP - identity provider | OIDC - OpenID Connect | SAML - Security Assertion Markup Language | RBAC - role-based access control | ABAC - attribute-based access control | SRE - site reliability engineering

Context, not internals. The diagram establishes people, organisational roles, the single Linebooker system boundary and owned-versus-external responsibilities. A customer or transporter organisation is a participant in the marketplace; it is not a deployment region or a NATS account.

Marketplace participation

Shippers create demand; transporters supply capacity; drivers execute work. Organisation membership provides the business context for every user action.

Linebooker responsibilities

Linebooker operates the logistics business. Linebooker Tech provides and runs the multi-tenant SaaS platform supporting that business.

Trust and sovereignty

External identity proves who a user is. Linebooker decides what they may do and applies country policy to regulated processing, transit and storage.

Linebooker Logistics SaaS - Container Architecture

Scope: separately runnable applications, services, messaging, workflow and stores inside the proposed Linebooker system. Audience: architects, engineering leads, security and operations. Regions, instance counts and country placement belong in the separate Deployment view.

Separately runnable containers and distinct state roles. Relationships are intentionally representative rather than exhaustive. The diagram identifies the transports and state responsibilities that shape the platform; the regional Deployment view will place instances of these containers into South Africa, Australia and Botswana cells.

● **Trust is resolved before business work**

External identity proof is converted into Linebooker tenant, organisation, membership and attribute context before a business service accepts a command.

● **Messaging has explicit roles**

NATS Core carries request/reply and selected live subjects. JetStream retains durable domain facts. Temporal owns workflow progress and retry state.

● **State remains deliberately distinct**

PostgreSQL is operational truth, projections and KV are rebuildable reads, the evidence repository stores documents, and audit storage follows masking and residency policy.
